spikes for blood sampling disposal channel

the output of baked blood occurs due to pressure

- Lactate mmol/l
- Creatinine mmol/l
- Saturation %

saturation level = total ratio of saturated glycated hemoglobin from which lactate is consumed creatine level = the amount of active substance that ensures the performance of muscles in acidified form; Lactate level = recommended limit before muscle oxidation begins In the case of professional triathletes, where the total number of distances exceeds 7 hours, on the final renounces, the athlete allows you to exceed the parameters of muscle acidification to go beyond the anaerobic limit, increasing the speed, thereby improving the total time. With a supply of a sufficient amount of creatine, the robotic ability of muscles in acidified form increases many times over the time range. Goal = to calculate the starting point when the athlete can go beyond the anaerobic threshold by starting to consume creatine to the finish line.
